NOTE.— NA—data not available (i.e., mitochondrial genome has not been sequenced; thus, we were unable to search the nuclear DNA for NUMTs).

^a Blast parameters were as follows: BlastN (version 2.2.23) with an expectation value of 0.0001; a word size of 11; match and mismatch scores of 2 and –3, respectively; and gap cost values of 5 (existence) and 2 (extension). Multiple organelle DNA hits to the same nuclear DNA regions were counted only once. Regions of nuclear DNA that contained tight clusters of NUPTs/NUMTs (i.e., sections of organelle-like DNA interrupted by genomic sequence that did not show sequence identity to organelle DNA) were not counted as a single NUPT/NUMT but as separate hits. See [supplementary table S3](#) (Supplementary Material online) for references and notes on the number of organelles per cell.

^b *S. moellendorffii* and *P. patens* both contain cells that are polyplastidic, but for the purpose of this study, they are considered “effectively monoplasticid” because mitosis and meiosis only occurs in cells that contain a single plastid (Brown and Lemmon 1990).
